Stability and aggregation of lipid bilayer

membranes in the presence of small unilamellar vesicles. In the presence of small unilamellar vesicles, the surface area of lipid membranes undergoes a biphasic change from lateral to a monolayer due to attractive forces between vesicles, which is followed by a biphasic change in surface area due to repulsive forces between vesicles. It is hypothesized that the initial depression in the surface area is due to the lateral-to-monolayer transition for the vesicles rather

than to the aggregation of the lipid membranes for the latter transition. Experiments were designed to study the time dependence of both the transition and the aggregation of lipid membranes in the presence of vesicles. For this purpose, thermotropic and spectroscopic characterization was used. The results obtained show that the vesicle approach is the initiation event of the lateral to monolayer transition and the aggregation of lipid membranes. Ask HN: How
