. Comparative effectiveness of ultrasound-guided breast biopsy for women with screen-detected nonpalpable breast lesions. To evaluate the comparative effectiveness of ultrasound-guided core needle biopsy (CNB) and vacuum-assisted core needle biopsy (VACNB) for women with screen-detected nonpalpable breast lesions. Between September 1, 2005, and October 31, 2009, we evaluated data from 1430 consecutive women in 649 screening centers in the United States who underwent ultrasound-guided CNB and VACNB for suspicious mammographically detected nonpalpable lesions. Women were classified according to imaging characteristics, lesion size, and patient age. The main outcome was a histopathologic diagnosis of malignancy. Lesions considered benign by the initial radiologist were upgraded to malignant at surgical excision or biopsy. Sensitivity, specificity, positive and negative predictive values, and positive and negative likelihood ratios of the different biopsy strategies were estimated, together with the likelihood of an upgrade to malignancy at the next follow-up. Sensitivity, specificity, positive and negative predictive values, and positive and negative likelihood ratios of ultrasound-guided CNB, VACNB, and surgery were 75.5% (95% confidence interval [CI], 73.5%-77.4%), 99.1% (95% CI, 98.7%-99.4%), 89.3% (95% CI, 86.5%-91.8%), 93.5% (95% CI, 91.5%-95.1%), and 0.13 (95% CI, 0.09-0.19), respectively. The likelihood of an upgrade to malignancy at the next follow-up was 6.6% (95% CI, 3.0%-13.0%), 8.5% (95% CI, 5.4%-12.8%), and 2.0% (95% CI, 1.0%-3.9%), respectively. Among women with mammographically detected nonpalpable breast lesions, the efficacy of ultrasound-guided CNB for histologic diagnosis is better than that of VACNB, with lower likelihood of upgrade to malignancy.
