.A pure oxide semiconductor generally has a wide forbidden band gap energy, and thus is applied as a material for a high-efficiency photoelectric conversion device. Among such oxide semiconductors, a thin film of an oxide semiconductor that has a cubic lattice structure in the surface of the crystal (cubic lattice structure) has not only a favorable electrostatic characteristic and a wide forbidden band gap energy, but also is easy to form into a thin film. As an example of such a thin film of an oxide semiconductor, there is a thin film of a hexagonal wurtzite crystal (hexagonal lattice structure) having a crystal symmetry, that is composed of hexagonal rings in the surface of the crystal and has a uniform band gap energy. The thin film of an oxide semiconductor has been attracting attention as a candidate material for a channel region of a non-volatile memory device and a switching element of a display device, or the like. As a thin film of an oxide semiconductor having a hexagonal lattice structure, a heteroepitaxial thin film that has grown by epitaxially growing a hexagonal wurtzite oxide thin film on a sapphire substrate or a SiC substrate is known (e.g., see Patent Document 1). In such a thin film of an oxide semiconductor having a hexagonal lattice structure, the film is easily influenced by the bond state of the substrate, or the like. This is because, in the heteroepitaxial thin film, there is no uniform orientation, and the film does not grow in a vertical direction with respect to the surface of the substrate. For this reason, there is a problem in that, for example, in a thin film of an oxide semiconductor that is used as an electrode of a non-volatile memory device and an element of a pixel, the thin film may be deteriorated and a problem in that a short may occur between the thin film and the upper or lower electrode, which are used in the non-volatile memory device and the element of the pixel. Patent Document 1: Japanese Laid-Open Patent Publication No. 2003-89238Q: Passing arguments to constructor of superclass What is the best way to pass arguments to a constructor of superclass in C++? This is a very basic question, but I spent a long time trying to find answer to this. I am asking because most of

The new series were all written by Dark Shadows co-creators Dan Green and Ron Marz, and they told a consistent continuity that continued from the '60s PBS series. The new books quickly proved to be very successful with fans, and when Tellos Press announced its plans for bringing all the Dark Shadows stories into print, there was just one problem: They didn't have the rights to do that. In early 2010, Dark Shadows creator Dan Green and Ron Marz announced a fan-fiction project that would create an alternate continuity in the Dark Shadows universe by connecting to an annual ritual in which the characters of the series go through resurrection-style revivals. This ritual, known as the Dark Carnival, has been seen on TV in various incarnations through the years, most notably in the fourth season of the '60s d0c515b9f4
