
Stratos Micra 25 Software Download HOT!

22 6.0 Orientation & Installation The Stratos-Micra 100 detector cannot be installed upside down if the sensor is to measure heat radiation. This can be verified by the fact that the detector, when attached in the correct orientation, will create an air flow at a temperature which is significantly higher than when the detector is installed upside down. Page 23 27 8.0 Sampling Pipe System When designing a smoke testing installation with Stratos-Micra 100 you should ensure that the sampling pipe exhaust outlet is vented outside. This is not possible in all locations. A suitable position for this is on the rear of the building where there is a reasonably good flow of cooling air. It is important to note that a sampling pipe must be completely emptied of air before the pipe is covered with plasterboard or other non-porous material. The plasterboard or other non-porous material should be chosen so that it is heat resistant. The fire panel can be used to monitor the flow of air through the sampling pipe and detect which pipe inlets or sample points have become blocked. The system should be designed to read the flow rates through the sample points manually and this may be done by switching the switch HW1 which turns off the flow meter and the fire panel signal light. Please note that a low reading means a blocked pipe. A high reading means the fire panel is incorrectly reading the flow rates through the sampling points. Page 28 28 7.4 Faulting The fire panel should be installed such that the system status LED is facing away from the fire panel. The fire panel status LED and the alarm LED on the detector communicate via a common low output. A fault in the fire panel may cause a failure of the fire panel status LED but not the alarm LED. This is because the alarm LED is externally triggered by the fire panel and so the fire panel is the preferred source of information. In the event of a failure in the fire panel status LED both the alarm LED and the fire panel status LED should be extinguished. 8.2 Power Supply The Stratos Micra 100 should be provided with a 12 VDC external power supply. This should have the following connections: 12 V DC - + Ground - - Ground Stratos Micra 100 board - + Trigger Probe lead 240 V AC supply (optional) - Supply Lead The 240 VAC supply should only be used if the detector is set to provide back-up power to the detector. 8.3 Manual Operation Using the manual switch located on the back of the detector enable the fire panel status LED and the alarm LED to illuminate. The fire panel status LED is typically in red and the alarm LED is typically amber. Once the detector has been set up, a fire can be defined by the fire panel status LED and the alarm LED illuminating together. Once the fire is defined the fire panel status LED and the alarm LED will change to a different combination of colours to indicate the fire has been extinguished. A typical fire panel status (colour) sequence is illustrated below.

37 9.1 Avoiding a fire Introduction to the Stratos-Micra 100 and the Add-On Pak Firing can be dangerous. To avoid getting burnt, it is recommended that when using a Stratos-Micra 25 in a building, the following should be observed: Never fire a Stratos-Micra 25 on top of combustible material or insulation. If this can not be avoided, then use high chemical or explosive fire retardants around the area to contain any fire. The fire protection performance of stratosphere protection systems and add-on paks is based on these principles.

The relative fire-resistance class is 3rd listed. Fire resistance ratings are based on UL 94V-0. You can obtain a copy of the product ratings from your local

Hammarlund distributor or from our technical support service at. Please do not rely solely on advice from the suppliers or manufacturers of these products in assessing the safety of an installation.

9.2 Not an expert user Software issues It is important to be aware of some software features that may affect the operation of the interface. On the main PCB are two DIP switches labelled

S1 and S2. If these are set to the ON position, the detector will be powered up and ready for use. If S1 is set to the OFF position, then the detector will remain powered down and the unit is not ready for use, as no stimuli can be delivered to the unit to make it respond. A single coil lens shutter will open when the S1 switch is set to the ON position. This function does not work if the

SenseNet loop is powered up. In the case of a flashing illuminated dome, this function will cause the flash rate to change as the S1 switch is toggled between the OFF and ON positions. As the S1 switch is set to the OFF position, the detectors will count flashes at a standard rate of 10Hz. As the S1 switch is toggled to the ON position, a percentage of the previous 10Hz count rate will be delivered as flashes. The percentage delivered as flashes is 0, 1, 2, ..., 50 per second. This function is designed to allow you to calibrate the detectors for the number of flashes per second of 10Hz delivered. As this delivers a percentage of the 10Hz flashes, no flashing of the dome will occur. This can be useful if you are setting up an alarm system and are recording the number of flashes. The system will record and recognise the number of flashes and can then deliver that value when you receive a second set of stimuli. The value returned in this case is the number of 10Hz flashes received in the last 10 seconds (the same time interval used for counting by the Stratos-Micra 100/25). 5ec8ef588b
